1 General

MoBPS is an R-package to simulate complex and large scale breeding programs with focus on livestock and crop populations. Simulations are performed on an individual basis. MoBPS is a versatile tool, providing standard procedures applied in animal and plant breeding like GBLUP and OGC, but also allowing to use own selection schemes while still controlling the simulation of phenotypes, meiosis and costs of the simulated scheme. The actual process of the simulation can be split up into two steps: the creation of a starting population and the simulation of breeding processes.

As it is our goal to provide a lot of flexibility while performing the simulation, there is a need of many parameters – luckily only a few of those will be needed for most simulations. For a better understanding of the workflow required to set up a simulation, we refer to section 16 for exemplary simulations. For a list of all input parameters and possible initializations, we refer to section 11.

Note that this package is still in active development.

For questions regarding the tool or how to set up your simulation feel free to contact me (Torsten.pook@uni-goettingen.de). We are always happy for questions as it really helps improve the tool and its documentation. For quick reply, it would help to provide a small example of our problem (ideally the population-list as a .RData object)

2 Installation

MoBPS requires R 3.3 or higher. We highly recommend the use of the packages RandomFieldsUtils (version 0.4.0+) and miraculix (0.7.8+) as they significantly reduce computation time when working with a high number of markers/individuals. All functionality is available without both package, but simulations can be significantly slower. For direct install via GitHub use the following line of code (this requires the R-package devtools):

```
devtools::install_github("tpook92/MoBPS", subdir="pkg")
```

This option is currently not available for miraculix and RandomFieldsUtils. RandomFieldsUtils is available on CRAN, miraculix will hopefully soon follow. Alternatively, miraculix, RandomFieldsUtils and MoBPS can be downloaded at <https://github.com/tpook92/MoBPS> and manually installed via the R function `install.packages()`. Usage was tested on Linux and Windows (under windows set `type="source"`, `repo=NULL`). The usage on Mac OS is currently not recommended. Commonly used Ensembl-maps are available in the associated R-package MoBPSmaps.

```
devtools::install_github("tpook92/MoBPS", subdir="pkg-maps")
```

For Windows the installation of Rtools is required. RandomFieldsUtils does require the package spam.

3 Citation

There is currently no paper published on our R-package. This will hopefully soon change. For so long we suggest using following to citations for the R-packages MoBPS and miraculix:

```

}

```

4 Creation of the starting population (*creating.diploid()*)

The input for the simulation of a breeding process is a population list. This list is created via *creating.diploid()*.

We provide exemplary genetic maps for some common species, which can be selected via the parameter **template.chip**. Note that primarily the number of chromosomes and their genetic length is imported at this step (especially not real markers with known allele frequencies, effects or base pairs). The maps provided via **template.chip** are “cattle” (Ma et al. 2015), “pig” (Rohrer et al. 1994), “chicken” (Groenen et al. 2009), “sheep” (Prieur et al. 2017) and “maize” (Lee et al. 2002). Alternatively, a genomic map can be inserted via the parameter **map** with exemplary maps being provide in the package itself or via import from Ensembl (section 9.9).

4.1 Importing/Generating of a genetic dataset

In case one has haplotype data for the founders/starting population this can be imported via the parameter **dataset** in form of a haplotype dataset:

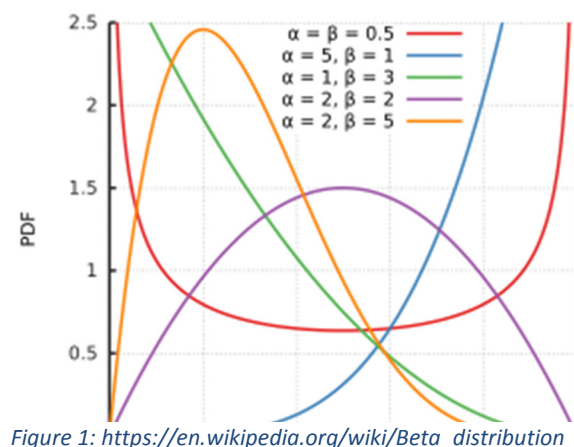

```

> dataset
      Indi1Haplo1 Indi1Haplo2 Indi2Haplo1 Indi2Haplo2 Indi3Haplo1 Indi3Haplo2 Indi4Haplo1 Indi4Haplo2
SNP1           1           1           1           1           0           1           1           0
SNP2           0           1           1           0           1           0           1           1
SNP3           0           0           0           1           1           0           0           1
SNP4           1           1           1           1           0           0           1           1
SNP5           0           1           0           1           0           1           1           1
SNP6           0           1           0           0           0           1           1           1
SNP7           1           0           1           1           1           1           1           0
SNP8           0           0           0           1           0           1           0           1
SNP9           1           1           0           0           0           0           0           1
SNP10          0           1           0           0           1           1           1           0

```

Datasets can also be imported via entering the path of the vcf file in the parameter **vcfpath**. The R-package vcfR is needed for this. Otherwise a dataset can be generated by setting the number of SNPs

(**nsnp**) and individuals (**nindi**) – we offer four possible modes to simulate starting haplotypes (“all0”, “allhetero”, “random”, “homorandom”) leading to haplotypes (000.../000..., 000.../111..., $X_1 X_2 X_3 \dots / X_4 X_5 X_6 \dots$ with $X_i \sim B(0.5)$ $X_1 X_2 X_3 \dots / X_1 X_2 X_3 \dots$ with $X_i \sim B(0.5)$). On default “random” is used. To use different allele frequencies, provide them in a vector starting from the first to the last marker in the parameter **freq**. To draw allele frequencies from an uniform/beta distribution set **freq** to “beta”. Shape parameters for the beta

distribution can be set via **beta_shape1** & **beta_shape2** (default: 1 & 1 – this is equivalent an uniform distribution).

To generate an LD and haplotype structure without using real data we recommend to start with one of the simple datasets and simulate some random/non-random mating generations using *breeding.diploid()* (cf. section 5). Wrapper functions for the automatic generation of those base populations in MoBPS are planned but not yet implemented.

If a *vcf* file is used for data import or a map is provided, the chromosome, marker name and base pair position are automatically imported. Alternatively, those can be provided via **chr.nr**, **bp** and **snp.name**. By doing this multiple chromosomes can be inputted jointly. If no input for **chr.nr** is provided all markers are assumed to be on the same chromosome (for more on the usage of a genetic map, we refer to section 4.2).

In case more markers are to be added to an existing population list set **add.chromosome** to TRUE and repeat the previous process with the population list as an additional input.

To specify the sex of each sample either assign each individual a probability to be female (**sex.quota**) or alternatively use a vector (**sex.s**) assigning each individual its sex (M=1, F=2).

4.2 Importing a genetic map

The user can provide a genetic map of up to five columns via the parameter **map**. The first column contains the chromosome of the respective marker, the second column the name of the marker, the third column the physical position of the marker, the fourth column the position in centimorgan and the last column the allele frequency in the population. All values not provided are automatically set to NA and values are used as input for **chr.nr**, **snp.name**, **bp**, **snp.position**, **freq**.

Alternatively maps can be imported via *ensembl.map()*. For more on this we refer to Chapter 9.9.

4.3 Simulating/Generating the genetic architecture underlying each trait

As the manual input of effects can be tiring we provide some automated procedures to simulate some common effect structures (additive, dominant, qualitative and quantitative epistasis) – if you don't need more you can just skip to section 4.3.2)

Note that this is the generation of an actual genetic value that is underlying each individual of the population. Normally you cannot observe this in reality, you typically cannot observe this, as traits will be caused by far more complex interactions and effects are not known. This, on the other hand, enables opportunities to evaluate a model fit given a known structure (e.g. GWAS hits can be compared to actual effect markers instead of previously identified markers or similar). Traits can be named via the parameter **trait.name**.

4.3.1 Custom-made genetic architectures

To simulate a custom-made genetic architecture we allow for effects caused by one (**real.bv.add**), two (**real.bv.mult**) or more SNPs (**real.bv.dice**). These effects can either be added directly while using *creating.diploid()* or added later using *creating.trait()*. To delete previously existing effects set **replace.real.bv** to TRUE. For multiple traits use lists as inputs for all parameters in this section with each list element containing information for one trait.

Input structure for the first two is a matrix with each row coding a single effect:

```
> real.bv.add
      SNP chromosome Effect 0 effect 1 effect 2
[1,] 120           1    -1.0         0.0         1
[2,]  42           5     0.0         0.0         2
[3,]  17          22     0.1         0.1         0
```

real.bv.add should be able to model any additive or dominance effects of single markers.

```
> real.bv.mut
      First SNP First chromosome Second SNP Second chromosome effect 00 effect 01 effect 02 effect 10 effect 11 effect 12 effect 20 effect 21 effect 22
[1,]      144           1       145           1      1.00      0.00      0.00      0.00      0.00      0.00      0.00      0.00      0.00      0.00
[2,]       6           3       188           5      0.37      0.16      1.33      1.49      1.58      2.51      0.38      2.12      0.98
[3,]       5          17         1          10      1.18      2.60      0.18      1.74      0.69      1.39     -1.21      0.96      1.94
```

real.bv.mut should be able to model any epistatic interaction between two markers.

To simulate even more complex effect structures use the parameter **real.bv.dice** allowing the modelling of effects caused by more than two SNPs.

Input for **real.bv.dice** is a list containing a list of all locations and a list of all effects:

```
> real.bv.dice
$location
$location[[1]]
      SNP chromosome
[1,]  11           1
[2,]  12           1
[3,]  16           4

$location[[2]]
      SNP chromosome
[1,]  14           2
[2,]  77           6
[3,]  15           9

$effects
$effects[[1]]
[1] 1.8212212 1.5939013 1.9189774 1.7821363 1.0745650 -0.9893517 1.6198257 0.9438713 0.8442045 -0.4707524 0.5218499 1.4179416 2.3586796

[25] 3.17261167 1.47550953 0.29005357
```

Each network of interacting markers is giving in the first list (location) and their effects are given in a second list (effects). Effects are sorted in following order: 0...0, 0...01, ... 2...2 – resulting in a vector with 3^n elements, where n is the number of markers involved in the effect.

Marker effects assign to positions that currently do not exist (e.g. SNP 100 on chromosome 1 in case chromosome 1 only contains 50 SNPs) are automatically removed from the stored effects unless **remove.invalid.qtl** is set to FALSE.

4.3.2 Predefined genetic architectures

In case of a predefined genetic architecture, all markers are assigned with the same probability to be drawn as effect markers. To exclude markers use a parameter **exclude.snps** containing a vector of all numeric positions of excluded markers. Numbering is consecutively starting with chromosome 1. Note that only markers, that are already included in the dataset, can be chosen as effect markers – so in case of more than one chromosome with no generation via **chr.nr** the effects should be added using *creating.trait* (cf. section 9.2) or in the last run of *creating.diploid()*.

The number of additive (**n.additive**) and dominate (**n.dominant**) QTL as well as effects caused by qualitative (**n.qualitative**) and quantitative (**n.quantitative**) epistasis can be included directly. To assign the variance, one can input a vector containing the variance for each effect (**var.additive**, **var.dominant**,...). On default, each variance is set to 1 and effects are drawn from a Gaussian distribution.

Qualitative epistasis is simulated by drawing 3 random effects for both involved markers, taking the absolute values from those, sorting them from low (0) to high (2) and multiplying those effects with each other. By this, we obtain the lowest effect for 00 and the highest for 22 with selection for alternative allele to be beneficial in all cases.

Quantitative epistasis is simulated by drawing 9 random effects and assigning the absolute values of two of those to the corner 02 and 20. All other combinations are assigned the minus absolute values of drawn random number.

To simulate more than one trait use vectors for **n.XXX** and lists for **var.XXX** instead.

4.3.3 Correlated Traits

To generate correlated quantitative traits selected the traits that should be correlated via **shuffle.traits** and provide the needed correlation in **shuffle.cor**. Note that QTLs are then assigned to the same markers to get correlations independent of the underlying LD structure. To set a correlation for traits with no underlying QTL, use **new.breeding.correlation**. As simulation is done via sampling from a Gaussian distribution and genetic traits do not fulfil all requirements of a dependent multivariate Gaussian distribution (which is here used to model dependency), the obtained resulting correlations can be different to the correlation set in **new.breeding.correlation** if non-QTL traits have correlations with QTL-traits. We are currently working on alternatives for this.

4.4 Position of Markers

For our simulations, the physical position in base pairs does not really matter – internally we are interested in a position in Morgan. We assume points of recombination to be distributed according to a Poisson distribution. On default, we assume markers to be equidistant with the total length of the chromosome in Morgan given by the parameter **chromosome.length** (default: 5). For joint generation of multiple chromosomes enter a vector instead. If none of the following options for the position of each marker are provided, markers are assumed to be equidistant- this will also minimize computation time and therefore should only be changed if needed.

Based on the physical positions entered in the parameter **bp** the position in Morgan can be derived by providing a conversion rate in **bpcm.conversion**. Note that tools like BEAGLE assume 100.000.000 bp per Morgan. For chicken we would recommend the use of 30.000.000 bp per Morgan.

Another way of entering the genetic position (in M) is via the parameter **snp.position** manually. Scaling can be performed internally by activating the parameter **position.scaling** and the **chromosome.length**. In addition, one should input a value for the number of base pairs before and after the last position (**length.before**, **length.behind**). Both should be chosen to be larger zero (default: 5) if scaling is performed.

For some applications, the recombination rate might not be the same for all individuals (e.g. male/female differences). To input an additional recombination map enter alternative positions in the parameter **add.architecture**. You can select which architecture is used for every parent in the actual simulation process.

5 Simulation of breeding processes (*breeding.diploid()*)

To perform the actual simulation of matings the function *breeding.diploid()* is used. Especially for that step, the sheer amount of different options can be deterring – in reality only a few parameters will actually be relevant. In this section, we will first discuss absolutely necessary parameters, their default options and afterwards discuss possible deviations. For exemplary simulation we refer to section 16. Note that you most likely can skip through some of the sections if you are not interested in changes in that dimension. There will be a lot of cases where there is the same parameter for the male and female part of the breeding program. We will limit ourselves here to the male parameter (**parametername.m**) – usage of the female version (**parametername.f**) will always be the same. The default setting for the female parameter is to be the same as the male parameter (NOT the default of the male parameter).

5.1 General setup

The output of *breeding.diploid()* is an updated population list. All newly generated individuals are added as an additional generation – to add them to a previously existing generation set **add.gen** to the generation you want to add to.

The number of newly generated individuals can be chosen via **breeding.size**. Input for this is a numeric value and sex of each offspring is randomly determined via **breeding.sex** (probability of a male offspring). To remove randomness set **breeding.sex.random** to FALSE or input a vector containing the number of new male/female individuals in **breeding.sex** instead.

To control which individuals are used in the mating procedure use the parameter **selection.size** (vector of size 2, containing the number of used male/female individuals). By default only the individuals of the last generation and class 0 (this is usually all and you will realize when this is not the case) are used. Classes can for example be used to model migration in store groups of different genetic origin but same sex and time of existence (generation).

To control which individuals are used every cohort generated can be named via **name.cohort** in *breeding.diploid()* & *creating.diploid()*. The individuals used in the selection procedure can be chosen via **selection.m.gen**, **selection.m.database** and **selection.m.cohorts** (paternal side) and same syntax for the maternal side. In the old version of the code, this is equivalent to the use of **best1.from.cohorts** and **best1.from.groups** that are still alternative input parameters for **selection.m.database** and **selection.m.cohorts**.

To combine individuals to a new cohorts of individuals set **combine** to TRUE. This will generate a new cohort of all selected individuals - do not combine male and females individuals!

On default the selection of individuals is done at random (For more on this we refer to 3.4).

To select the individuals of which class to consider in the selection procedure, use the parameter **class.m**, containing a vector of all usable classes. To control the class of the new individuals use the parameter **new.class** (default 0). Classes of all cohorts added are automatically added to the vector of considered classes (**class.m**) unless **add.class.cohorts** is set to FALSE.

To generate multiple offspring from the same dam/sire pair set **repeat.mating** to the desired number.

Both the time of the generation of new individuals (**time.point**) and the type of the mating (**creating.type**) can be stored. Both parameters are mostly used internally in the web-based application and are automatically tracked internally.

5.2 Control of heritability, breeding values, genotypes and phenotypes

For each individual, an underlying true genetic value is calculated for each trait. Based on this, phenotypes can be generated. For with individuals to generate new phenotypes can be controlled via **new.bv.observation.gen**, **new.bv.observation.database** and **new.bv.observation.cohorts**. For a quick input of all individuals previously not phenotyped set **new.bv.observation** to “all” or “non_obs” for all or all previously not phenotyped individuals. On default for each individual at most one phenotype is generate. Set **multiple.observation** to TRUE to allow for more than one observation per individual. To generate multiple observations in a single run of *breeding.diploid()* set **n.observation** to that number. Note that the number of times an observation for an individual is generated does matter since the environmental variance will be reduced with each observation previous observations will be used). To model a correlation between the environmental variances for different traits set provide the desired correlation matrix via **new.phenotyp.correlation** (this can also be done in *creating.diploid()*). For the simulation of correlated genetic values we refer to section 4.3.3.

The environmental variance σ_e can be controlled by the usage of **sigma.e**. This can either be set to a fixed numeric value or be estimated to fulfill a target heritability. For the second possibility, the genetic variance is calculated based on the individuals specified in **sigma.e.gen**, **sigma.e.database** and **sigma.e.cohorts** and the needed environmental variance is then calculated by the usage of a predefined **heritability**. You can also use the environmental variance of the previous simulation by setting **use.last.sigma.e** to TRUE. A manual change of the genetic variance **sigma.g** is not recommended but in principle possible (this will only affect the breeding value estimation). On default it is estimated using all individuals used in the current breeding value estimation (set **forecast.sigma.g** to FALSE to deactivate). To specify which groups to use to estimate σ_g use **sigma.g.gen**, **sigma.g.database**, **sigma.g.cohorts**.

For newly created individuals the phenotype is set to the mean of the phenotypes of both parents. Alternatively, one can set it to zero or create an observation by setting **new.bv.child** to “zero” or “obs” instead of “mean”. In case of generating individuals via **copy.individual** one can also use “addobs” to import existing observations but also potential generate additional ones via **n.observation**. Estimated breeding values are also kept unless **copy.individual.keep.bve** is set to FALSE.

To select the share of individuals genotyped use the parameter **share.genotyped** or select it manually via **genotyped.s** (in concordance to **sex.s** in *creating.diploid()*). In case an individual is generated via **copy.individual** the genotyping state is keep and the share of previously not genotyped individuals that is now genotyped can be controlled via **added.genotyped**.

In some applications, the genetic value of the individual itself is not of importance – instead the performance of its offspring is of relevancy. To select for which individuals to import offspring phenotypes use **offspring.bve.parent.gen**, **offspring.bve.parent.database** and **offspring.bve.parent.cohorts**. Unless specified in **offspring.bve.offspring.gen**, **offspring.bve.offspring.database** and **offspring.bve.offspring.cohorts** all offspring are considered here.

For better comparison of and between breeding values it is possible to standardizing breeding values before the first generation by activating **standardize.bv**. By this the average breeding value is set to **standardize.bv.level** (default: 100) – for the calculation of this, the average of the individuals in generation **standardize.bv.gen** (default: 1) is used.

Scaling in case of index selection with multiple traits is performed in the selection process itself.

5.3 Breeding value estimation

To perform selection one can perform breeding value estimation. To activate this set **bve** to TRUE. In the simplest case, one has to input which groups to use in the breeding value estimation via the parameters **bve.gen**, **bve.database** and **bve.cohorts**.

As there are a lot of different ways to perform breeding value estimation we implemented multiple variants:

1. GBLUP with assumed known heritability and direct solving of the mixed model without REML variance component estimation
2. Bayesian approaches implemented in BGLR
3. GBLUP using EMMREML
4. GBLUP using sommer
5. Pedigree-based BLUP via breedR
6. Parent/Grandparent mean
7. Own function

In any case estimated breeding values are entered for all individuals unless **bve.insert.gen**, **bve.insert.database** or **bve.insert.cohorts** directly classifies for which groups breeding values are to be entered. The accuracy of the breeding value estimation is automatically reported unless **report.accuracy** is set to FALSE.

For the calculation of G we offer multiple methods with **computation.A**="vanRaden" being the default (VanRaden 2008). Alternatives include "kinship", "CM", "CE" (Martini et al. 2017) and the non-Z-standardized version of the vanRaden method ("non_stand"). In case "kinship" is selected the depth of the pedigree has to be provided via the parameter **depth.pedigree**. Individuals with no observed phenotype start with a value of 0. Internally all phenotypes that are exactly 0 are handled as an NA – suppress this by setting **bve.0isNA** to FALSE (note that only methods 1./2./4. are able to handle NAs in the data).

To not perform statistical breeding value estimation but instead using the phenotypes as breeding value estimates set **phenotype.bv** to TRUE.

As the presence of true effect markers in the dataset might be a strong assumption one can set **remove.effect.position** to not use markers associated with any traits in the breeding value estimation.

To only included individuals with a certain class set **bve.class** to a vector containing all classes to consider.

In case individuals were generated via **copy.individual** (this is especially relevant for the web-based application) each individuals is only used at most once. To consider the same individual multiple times set **bve.avoid.duplicates** to FALSE. Note that cloning will not lead to the same ID.

To active the use of the single step genomic relationship matrix set **singlestep.active** to TRUE – otherwise non-genotyped individuals are not considered in the breeding value estimation unless **remove.non.genotyped** is set to FALSE.

5.3.1 Direct approach with known heritability

Main advantage of a direct estimation is a massive improvement in computation time as the usually necessary REML estimation takes most of the time. In practice it might not be realistic but since genetic

values are known it is possible. Note that this is still an empirical measure that can change when using different individuals in the estimation process. Especially for bigger populations heritability estimation should not be problematic and is not performed in each breeding value estimation in practice as well. To instead estimate the additive genetic variance using a parental model activate **estimate.add.gen.var**.

In case of missing phenotypes estimates will be based on (VanRaden 2008) method 2. This will also be used in case of the use of single step. Alternatively one can use rrBLUP based estimates by setting **bve.direct.est** to FALSE. Note that this is slower and requires the presence of individuals that are phenotyped and genotyped.

5.3.2 Bayesian approaches (BGLR)

For performing Bayesian methods we are using the R-package BGLR. To activate the usage of BGLR set **BGLR.bve** to TRUE. On default a Reproducing-kernel-hilbert-space is used – alternatively one can use BayesA, BayesB, BayesC by setting **BGLR.method** to “BayesA”, “BayesB”, “BayesC” instead of “RKHS”.

To control the number of the burn-in and iterations use **BGLR.burnin** and **BGLR.iteration**. To deactivate printing of results of interim steps set **BGLR.print** to FALSE (equal to verbose=FALSE in BGLR). On default BGLR will generate some internal files in its computations. To select a path of where to store them chose it via **BGLR.save**. Especially when parallelizing thousands of simulations BGLR tends to crash when the same path is used multiple times. Activating **BGLR.save.random** will hinder this.

5.3.3 GBLUP (EMMREML)

Traditional GBLUP including variance component estimation using REML is performed by using the package EMMREML. To activate the usage set **emmreml.bve** to TRUE. EMMREML does not support missing phenotypes and therefore can only be used if phenotypes for all individuals in the BVE are available (if not use the direct approach, sommer or rrBLUP).

5.3.4 GBLUP (sommer)

Traditional GBLUP including variance component estimation using REML is performed by using the package sommer. To activate the usage set **sommer.bve** to TRUE. Sommer does support missing phenotypes.

To activate the use of the multi-trait model implemented in sommer use **sommer.multi.bve** to TRUE. Note that this will take substantially longer than single trait models.

5.3.5 GBLUP (rrBLUP)

Traditional GBLUP including variance component estimation using REML is performed by using the package rrBLUP. To activate the usage set **rrBLUP.bve** to TRUE. rrBLUP is about 2.5 times as fast as sommer for breeding value estimation. We observed slightly worse accuracies in some of our tests.

5.3.6 Pedigree-based (breedR)

Traditional breeding value estimation using pedigree data. To activate set **breedR.bve** to TRUE – especially for bigger populations this is much faster computation wise. Have to double-check estimation technique used – heritability seems to be underestimated!

Alternatively the pedigree-based relationship matrix can also be used in all other methods by setting `computation.A` to “kinship”. Takes about the same time as with other relationship matrices then (No usage of high number of zeros in the dataset).

5.3.7 Parent/Grandparent mean

To use the mean performance of the parents / grandparents as the breeding value use **bve.parent.mean** / **bve.grandparent.mean**. On default breeding value estimates for the parents are used and if those are not available phenotypes. Alternatively one can select to use breeding values only (“bve”), phenotypes only (“pheno”) or genomic values (“bv”) via the parameter **bve.mean.between**.

5.3.8 Own function

Instead of performing breeding value estimation inside of *breeding.diploid()* one can implement his own methodology by exporting all information needed to those computations and inserting own breeding values estimates via the function *insert.bve()*.

According code could look like this:

```
# Simulate Phenotypes for generation 4 with heritability 0.4
population <- breeding.diploid(population, heritability = 0.4,
                              sigma.e.gen = 4,
                              new.bv.observation.gen=4)

# Export genotypes and phenotypes for generation 4
genos <- get.geno(population, gen=4)
phenos <- get.pheno(population, gen=4)

# Here you perform your own method to assign breeding values to each individual
bve <- runif(ncol(genos)) # This is probably not the best technique for this =)

# Import breeding values estimated for generation 4
bves <- cbind(colnames(genos), bve)
population <- insert.bve(population, bves=bves)
```

For details on exporting functions, we refer to section 6. For details on importing function, we refer to section 7.

5.3.9 Calculating marker effects & GWAS

For some applications (e.g. gene editing) it is necessary to identify causal markers. Although marker effects are known in a simulation, in practice one has to identify them. Options here are either a direct calculation of the effect size of each marker based on the computations performed in 5.3.1 (rrBLUP) or the performance of a GWAS-study without correction for population structure. Methods can be activated by setting **estimate.u** or **gwas.u** to TRUE.

In case of a GWAS study one can additionally select the groups used in the study by setting **gwas.gen**, **gwas.database** and **gwas.cohorts** (default is same as for breeding value estimation). As a value for y, one can use the phenotype (“pheno”), true breeding value (“bv”) or the estimated breeding value (“bve”). Additionally it might be necessary to standardize the y value by the mean of the group by activating **gwas.group.standard**. Note that this is a basic implementation of GWAS with no correction for population structure or similar.

5.3.10 Calculation of reliabilities

Reliabilities are not derived in any of the used R-packages. In the direct approach (Chapter 5.3.1), they can be derived by setting **calculate.reliability** to TRUE according to (VanRaden 2008).

5.4 Selection techniques & mating strategies

Selection of the individuals for matings in the following generations is of key importance for any breeding program. Especially here, one is limited to the techniques that work in the species one wants to simulate. On default settings the selection of the new founders is done totally random. To use estimated breeding values as a selection criteria set **selection.m** to “function”. To ignore the best selected individuals set **ignore.best** to that value – note that this value will be internally subtracted from **selection.size**. E.g. to simulate mating between the top 100 female individuals with the third and fourth best male individual set **selection.size** = c(4,100) and **ignore.best**=c(2,0). To exclude specific individuals from the set of individuals to select from use **reduced.selection.panel.m**. The vector should contain all individuals to use (e.g. 1:10 when selecting from the first ten individuals).

To store details on which individuals were selected, which mating were performed and the currently estimated breeding values activate **store.breeding.totals**.

Selection can be performed based on the phenotype, genetic value or the breeding value estimates. To select what to use set **selection.criteria.type** to “pheno”, “bv” or “bve” (default: “bve”).

5.4.1 Multiple traits

When working with multiple traits, the selection of the best individuals is typically done by the use of a combination of those traits. All single values can either be added up directly (**multiple.bve**=“add”) or one can use a selection index just accounting for the ranking (**multiple.bve**=“ranking”). To reduce scaling problems for different traits one can use **multiple.bve.scale.m** to standardize the variance in each trait. Note that this scaling in the cohort mode is for all individuals together whereas in the old selection modes it is done per group (! – needs to be the same!!!). Additionally, each trait can be assigned a weighting via **multiple.bve.weights.m**.

To derive the ideal index based on phenotypic/genotypic variance, reliabilities and economic gains per unit according to (Miesenberger 1997) set **selection.m.miesenberger** to TRUE. Economic gains can be provided in **multiple.bve.weights.m**. On default, the gain has to be provided per standard deviation of the breeding value estimations. Alternatives can be provided in **selection.miesenberger.w** (default: “bve_sd”) and are per unit (“unit”) and per phenotypic standard deviation (“pheno_sd”).

In case reliabilities are not derived (Chapter 5.3.10), they need to be estimated. On default this is done by dividing the standard deviation of the breeding value estimation by the standard deviation of the phenotypes. Alternatives can be entered in **selection.miesenberger.reliability.est**, as the direct use of

the heritability (“heritability”) or the actual calculation according to the correlation between breeding value estimates and true underlying genomic values (“derived”) which is of course not possible in practice but should be the most accurate.

5.4.2 Higher procreation of genetically favored individuals

Genetically favored individuals tend to procreate more often. To model this set a ratio between the likelihood of the best individual to mate compared to the worst individual (in the group of selected individuals) in **best.selection.ratio.m**. This ratio is the ratio between the frequency the best selected individual and the worst selected individual. All other frequencies are then calculated linearly. E.g. in a group of selected individuals with breeding values 105, 103 and 100 with a ratio of 6 the relative frequencies are of 6,4,1 (this just is a linear function – comp for individual 2: $(103 - 100) / (105 - 100) * (6 - 1) + 1$). Criteria behind can be either “bv”, “bve” or “pheno” and can be entered in **best.selection.criteria.m**. To manually enter the probability of each individual in the group of selected individuals input a vector with frequencies for each individual in **best.selection.manual.ratio.m**. Individuals selected are sorted with the individual with the highest estimated breeding value being the first one.

This does not require breeding value estimation and can also be used to simulate slow natural selection processes over thousands of generations.

Higher procreation is also relevant for optimum genetic contribution theory and the use of **ogc** will automatically change these parameters accordingly (section 5.4.8).

5.4.3 Maximum number of offspring per individual

To control the maximum number of times each individual is used for reproduction set **max.offspring**. Either enter a numeric if that boundary is for both sexes or a vector with the first value coding the maximum for male and the second the one for female.

5.4.4 Plant breeding (no-sexes & selfing & DH-production & cloning)

For some applications the sex of an individuals is not relevant (or and individual does not even have a sex). Even though a sex is still stored internal it might be neglectable for the application at hand. In this case one can allow matings between individuals from the same sex by usage of **same.sex.activ**. The probability to select a female individuals as a parent can be set via **same.sex.sex** (default=0.5). To additionally allow for selfing set **same.sex.selfing** to TRUE. Probability for this mating is the same as any other mating combination.

To perform exclusively selfings activate **selfing.mating** and selected the probability to use a female parent via **selfing.sex**.

To generate doubled haploid lines active **dh.mating** and selected the probability to use a female parent via **dh.sex**.

To generate an exact copy of an individual active **copy.individual**. Instead of simulating meiosis both chromosome sets of the selected first parent (usually father) will be copied (to copy female individuals use **same.sex.activ** and set the probability to use females to 1 (**same.sex.sex=1**)).

5.4.5 Generate offspring for all sire combination

To generate offspring from each possible parental combination set **breeding.all.combination** to TRUE. In case only individuals from one sex are selected sex is ignored when deriving potential matings. **Breeding.size** still has to be set.

5.4.6 Targeted/Fixed mating/Manual selection of individuals

If none of the previously described methods works for your simulation, you can also just manually enter a list of all matings that should be performed. For this, use the parameter **fixed.breeding**. To perform targeted mating in the group of the best individuals use **fixed.breeding.best**. Here each row just contains the sex and position in the list of selected individuals. In both cases an additional column can be added coding the likelihood of the offspring being female.

5.4.7 Gene-Editing

With increasing popularity of methods like CRISPR/Cas9 one might be interested in performing gene editing to increase the genetic gain. Gene editing can be activated by setting **gene.editing** to TRUE. The number of edits can be controlled via **nr.edits** and effect markers are picked via usage of the predictions via rrBLUP/GWAS in section 5.3.9. We only count actually performed edits – if an allele is already beneficial the next best marker is edited instead. Although in practice not possible the first integrated way of editing is to edit all selected individuals – this technique is also performed in the approach PAGE (Jenko et al. 2015) and our counter version (Simianer et al. 2018).

As a more realistic scenario, we also allow for the editing of offspring via **gene.editing.offspring**. To only perform editing on male or female individuals set **gene.editing.offspring.sex** / **gene.editing.best.sex** to 1 (male) or 2 (female).

Note that traditionally modelled effects often neglected strongly deleterious mutations and we are here assuming that 100% of all edits will work, all possible offspring will survive the procedure and traits are as simple as designed (usually single marker QTL).

5.4.8 Optimum genetic contribution

To use optimum genetic contribution theory from the group of selected individuals set **ogc** to TRUE. The target increase of the average relationship can be selected via **ogc_cAc**. On default the increase is minimized. MoBPS is used the traditional formula according to (Meuwissen 1997). One can also provide on weightings via **best.selection.manual.ratio.m** (Chapter 5.4.2) and/or **fixed.breeding** (Chapter 5.4.6). We are also willing to implemented alternatives if they are needed/wanted.

5.5 Genetic architecture

When simulating meiosis we are accounting for recombination and mutation. We are assuming that recombination points are Poisson distributed with one expected point of recombination per 1 Morgan. To change this, set **recombination.rate** to the needed value. To not use a fixed value but a step-function instead use **recom.f.indicator**. Additional genetic architectures can be added the same way

as in *creating.diploid()* via **add.architecture**. To select the genetic architecture of recombination for set **gen.architecture.m** to the architecture that should be used for males.

Regarding mutation rates we are assuming that each marker has the same probability for a mutation – this can be changed via **mutation.rate** (default: 10^{-5}). A mutation back to the reference is assigned the probability of **remutation.rate** (default: 10^{-5}). Those values tend to be a lot higher than what you would expect in nature. Depending on the base pair one would expect something around 10^{-8} for a random loci.

Duplications are implemented but the modelling is absolutely adhoc and probably needs refinement – talk to me if you plan to do something in that direction!

5.6 Other

5.6.1 Culling / Death

5.6.1.1 Culling module (Web-interface)

The new culling module is currently only available for cohorts and mainly intended for interface users. Here parameters settings will take care of itself. To manually execute this in R use **culling.cohort** to select for which cohort to execute the module. The age of the individual can be provided in **culling.time**. The name of the culling reason can be provided in **culling.name**. Additional one can provide two breeding values (**culling.bv1**, **culling.bv2**) and two culling probabilities (**culling.share1**, **culling.share2**). For all other genomic values the probability of culling this then derived with linear extension.

An index of weighting between traits can be selected via **culling.index** (similar to **multiple.bve.weights.m** – Chapter 5.4.1). On default, no genomic influence is assumed and all individuals are culled with the same probability (**culling.share1**).

5.6.1.2 Old module

Especially for cost calculation it might be necessary to know the time of death for each individual. A group of individuals can be reduced to **reduce.group** with each row coding generation, sex, number of individuals to keep, class. To set the selection criteria use **reduce.group.selection** (default: “random”).

5.6.2 Parameter for target-mating with J.W.R. Martini

Don't think anyone needs documentation here – code is specific to the planned paper with Johannes and does not generalize (quick and dirty - <https://github.com/Droogans/unmaintainable-code>)

martini.selection / Special.comp / Special.comp.add / Max_auswahl / Predict.effects / SNP.density / Use.effect.markers / Use.effect.combination

5.6.3 Allele-frequency per generation

To store the frequency of each allele per generation activate **store.effect.freq**.

5.6.4 Set a random seed

For repeatability it might be helpful to set a random seed in R. This can be done via the parameter **randomSeed** or directly performed in R using **set.seed()**.

5.6.5 save.recombination.history

To store the time of occurrence of each point of recombination activate **save.recombination.history**. This has to be done starting with the first generation and currently crashes after setting a new founder population (Currently nobody needs it! – but should be an easy fix!)

5.7 Storage & computation time

To store the time needed in each step of the simulation tool activate **store.comp.times**. For more details of the breeding value estimate you can additionally activate **store.comp.times.bve**. Activation of **Rprof** can provide even more information.

5.7.1 Reducing the size of the population list

Especially when simulating populations with lots of markers, individuals and/or generations, data storage can become a problem. As the internal structure of a population list is complex and manually deleting of things is not recommended –use following settings in *breeding.diploid()* instead:

delete.haplotypes: Vector containing all generations for which haplotypes no longer need to be stored (note that only founder generations are stored anyway – everything else is calculated on-the-fly)

delete.same.origin: Merge two adjacent segments with the same founding haplotypes (deletion of a recombination point with no influence)

delete.individuals: Vector containing all generations for complete deletion– to only delete one sex use **delete.sex** (vector contain sex to delete – 1 (male), 2 (female). Especially when the number of recombinations stored per individual, becomes bigger this is of relevancy.

5.7.2 Reducing memory needs in the BVE

To calculate the genomic relationship matrix, one has to perform matrix multiplication of a matrix containing $n \times p$ entries (individuals x markers). Note that for every entry only 2 bits are needed when using miraculix. Nevertheless, this can become extremely big – to reduce this, one can perform the calculation of G sequentially and only load a part of Z into memory at any time.

To activate this, set **sequenceZ** to TRUE. The number of markers in memory can be controlled via **maxZ** (default: 5000). Alternatively, one can put **maxZtotal** to control the total number of entries instead. As this is increasing the computation time, we first recommend to activation of miraculix by setting the parameter **miraculix** to TRUE when creating the founder population in *creating.diploid()*. For more on this we refer to section 9.12.

To speed up commutation one can use multiple cores by the usage of **miraculix.cores** (default: 1) or in case miraculix is not active **ncore**. The backend outside of miraculix is using doParallel but doMPI is supported as well – we highly recommend the use of miraculix instead.

Setting **fast.compiler** to TRUE will additionally activate a just-in-time-compiler (enableJIT(3)).

To save computation speed in the GWAS, one can use **approx.residuals** – this does not influence the order of the predicted effect markers but will influence p-values slightly.

5.7.3 Inverting G using miraculix

The inversion of $(G + I_n \cdot \lambda)$ can take a lot of time, is numerically unstable and might not even be possible at all if the matrix is not invertible at all. Instead of the standard cholesky procedure using `chol2inv(chol())`, the inversion can also be done in `RandomFieldsUtils/miraculix` by activating **chol.miraculix**. Leading to similar computation time – but also includes screening for semi definite matrices and an automatically changed algorithm, if needed, and thus proceeding without error.

5.7.4 On-the-fly calculation of haplotypes

To save memory, haplotypes are calculated on-the-fly. For this, the location of each recombination point (between which markers) has to be stored. In case one is working with equidistant markers, it basically takes no time. For other positions it might increase computation speed to provide a function that derives the last marker in front of a certain position in Morgan. This function can be entered via **import.position.calculation**. Only in extreme cases (lots of markers) this should even matter!

6 Exporting information from the population-list (get.XXXX)

Most of the data stored in a population list is highly compressed since saving haplotypes of all individuals of the dataset for all generations would in most cases exceed most local machines or even servers. For some applications (especially if one wants to perform his own fancy simulations without contacting the author and asking him to extent the package) it might be useful to understand the data structure behind. For that we refer to section 8. In most cases using our predefined export functions should be enough:

In what individuals one is interested in can be controlled by usage of the parameter **gen**, **database** and/or **cohorts**. Here **cohorts** and **gen** are vectors containing all generations/cohort to include whereas **database** contains a matrix with each row coding a group to export:

```
> database
      Generation sex
[1,]           1  2
[2,]           5  1
```

This **database** will export the information for all female individuals from generation 1 and all male individuals from generation 5.

6.1 get.genos

This function will export genotypes. To additionally output the base pair of the minor/major allele set the parameter **export.alleles** to TRUE. Each column contains one genotype with column names indicating sex, individual number and generation.

```
> genos <- get.geno(population,gen=3)
> genos[1:5,1:10]
```

	M1_3	M2_3	M3_3	M4_3	M5_3	M6_3	M7_3	M8_3	M9_3	M10_3
Chr1SNP1	1	2	1	0	2	1	2	2	2	1
Chr1SNP2	1	0	1	0	2	1	1	2	1	0
Chr1SNP3	1	0	1	1	0	1	0	1	0	1
Chr1SNP4	0	0	1	1	1	1	0	0	0	1
Chr1SNP5	1	0	1	2	1	1	0	0	0	0

6.2 get.haplos

This function will export haplotypes. To additionally output the base pair of the minor/major allele set the parameter **export.alleles** to TRUE. Each column contains one haplotype with column names indicating sex, individual number, chromosome set (currently only diploid individuals) and generation.

```
> haplos <- get.haplo(population,gen=3)
> haplos[1:5,]
```

	M1_3_set1	M1_3_set2	M2_3_set1	M2_3_set2	M3_3_set1	M3_3_set2	M4_3_set1	M4_3_set2	M5_3_set1	M5_3_set2
Chr1SNP1	0	1	1	1	0	1	0	0	1	1
Chr1SNP2	0	1	0	0	0	1	0	0	1	1
Chr1SNP3	1	0	0	0	1	0	0	1	0	0
Chr1SNP4	0	0	0	0	1	0	1	0	1	0
Chr1SNP5	1	0	0	0	1	0	1	1	1	0

6.3 get.bv / get.bve / get.pheno / get.reliability / get.selectionindex

These functions will export the true underlying breeding value ("bv"), the estimated breeding value ("bve"), the phenotype ("pheno"), the reliability for each breeding value estimation/trait ("reliability") and the selection index used in the last selection procedure ("selectionindex").

```
> bv <- get.bv(population,gen=1)
> bve <- get.bve(population,gen=1)
> pheno <- get.pheno(population,gen=1)
> bve[1:5]
[1] 45.95833 48.85317 31.53675 35.73686 49.55310
> bv[1:5]

> pheno[1:5]
[1] -22.230518 67.241256 -9.337895 -16.056936 101.497754
```

6.4 get.recombi

This function will export all points of recombination and the genetic origin of each segment. The structure here is a list of 4 elements with elements 1 (paternal) and 2 (maternal) containing recombination points and elements 3 (paternal) and 4 (maternal) containing the genetic origin.

Each row is coding the genetic origin between two points (generation, sex, individual number, chromosome set). In the example provided this would mean that the segment between 0.000 and 0.218 of the paternal chromosome originates from the second chromosome set of the 532nd female individual of the first generation.

Note that in addition to all recombination points the start and end points of chromosomes are also exported.

```

> recomb1 <- get.recomb1(population, gen=3)
> recomb1[[1]][[1]]
[1] 0.0000000 0.2183368 0.3517032 0.6187816 1.0718667 1.3089574 1.6053402 1.6390138 1.6627053 1.9827624 2.0846120

[3,] 1 1 78 1
[4,] 1 2 352 2
[5,] 1 2 352 1
> recomb1[[1]][[5]]
[1] "M1"

```

6.5 get.pedigree (1/2/3)

This function will export the pedigree. Individuals are coded by sex, individual number and generation.

```

> ped <- get.pedigree(population, gen=12)
> ped[1:10,]
      offspring father      mother
[1,] "M1_12"      "M2214_11" "W1776_11"
[2,] "M2_12"      "M2052_11" "W1125_11"
[3,] "M3_12"      "M1529_11" "W1904_11"
[4,] "M4_12"      "M1712_11" "W1256_11"
[5,] "M5_12"      "M221_11"   "W326_11"

```

Instead of character string with "M"/"W" indicating sex, one can also directly export a table with 9 columns indicating Sex (1/2), Generation(1,2,3,...) and individual number (1,2,3,...) in a numeric format by setting **raw** to TRUE.

To export grandparents use *get.pedigree2()*, to get both *get.pedigree3()*. In *get.pedigree2()* one can additionally export the share of the genome inherited by which grandparent by setting the parameter **shares** to TRUE.

```

> ped <- get.pedigree2(population, gen=12)
> ped[1:5,]
      offspring grandfatherf grandmotherf grandfatherm grandmother
[1,] "M1_12"      "M734_10"      "W2135_10"      "M2342_10"      "W313_10"
[2,] "M2_12"      "M1188_10"      "W1436_10"      "M489_10"       "W539_10"
[3,] "M3_12"      "M1702_10"      "W1860_10"      "M413_10"       "W1234_10"
[4,] "M4_12"      "M1560_10"      "W1211_10"      "M1649_10"      "W254_10"
[5,] "M5_12"      "M1649_10"      "W2093_10"      "M1593_10"      "W2390_10"
> ped <- get.pedigree3(population, gen=12)
> ped[1:5,]
      offspring father      mother      grandfatherf grandmotherf grandfatherm grandmother
[1,] "M1_12"      "M2214_11" "W1776_11" "M734_10"      "W2135_10" "M2342_10"      "W313_10"
[2,] "M2_12"      "M2052_11" "W1125_11" "M1188_10"      "W1436_10" "M489_10"       "W539_10"
[3,] "M3_12"      "M1529_11" "W1904_11" "M1702_10"      "W1860_10" "M413_10"       "W1234_10"
[4,] "M4_12"      "M1712_11" "W1256_11" "M1560_10"      "W1211_10" "M1649_10"      "W254_10"
[5,] "M5_12"      "M221_11"   "W326_11"   "M1649_10"      "W2093_10" "M1593_10"      "W2390_10"

```

6.6 get.cohorts

This function extracts all existing cohorts from the population list. Set **extended** to TRUE to also extract further information on the cohorts:

```

> get.cohorts(population)[1:5]
[1] "Founder_M"      "Founder_W"      "Cows"           "Bulls"          "Selected_bulls"
> get.cohorts(population, extended=TRUE)[1:5,]
      name      generation male individuals female individuals class position first male position first female time point creating.type
[1,] "Founder_M"      "1"      "50"      "0"      "0"      "1"      "0"      "0"      "0"
[2,] "Founder_W"      "1"      "0"      "50"      "0"      "0"      "1"      "0"      "0"
[3,] "Cows"           "2"      "0"      "50"      "1"      "1"      "1"      "1"      "2"
[4,] "Bulls"          "2"      "50"      "0"      "1"      "1"      "51"      "1"      "2"
[5,] "Selected_bulls" "3"      "10"      "0"      "2"      "1"      "1"      "1"      "1"

```

6.7 get.class

This function extracts the class of each individual:

```
> get.class(population, gen=1:2)
  M1_1 M2_1 M3_1 M4_1 M5_1 M6_1 M7_1 M8_1 M9_1 M10_1 M11_1 M12_1 M13_1
    0    0    0    0    0    0    0    0    0    0    0    0    0
M14_1 M15_1 M16_1 M17_1 M18_1 M19_1 M20_1 M21_1 M22_1 M23_1 M24_1 M25_1 M26_1
    0    0    0    0    0    0    0    0    0    0    0    0    0
...
W42_1 W43_1 W44_1 W45_1 W46_1 W47_1 W48_1 W49_1 W50_1 M1_2 M2_2 M3_2 M4_2
    0    0    0    0    0    0    0    0    0    1    1    1    1
  M5_2 M6_2 M7_2 M8_2 M9_2 M10_2 M11_2 M12_2 M13_2 M14_2 M15_2 M16_2 M17_2
    1    1    1    1    1    1    1    1    1    1    1    1    1
M18_2 M19_2 M20_2 M21_2 M22_2 M23_2 M24_2 M25_2 M26_2 M27_2 M28_2 M29_2 M30_2
    1    1    1    1    1    1    1    1    1    1    1    1    1
```

6.8 get.time.point

This function extract the time point of generation – this is mostly applicable when using the web-based application since there the first possible time point of generation is automatically calculated.

```
> get.time.point(population , gen=1:2)
  M1_1 M2_1 M3_1 M4_1 M5_1 M6_1 M7_1 M8_1 M9_1 M10_1 M11_1 M12_1 M13_1 M14_1 M15_1
    0    0    0    0    0    0    0    0    0    0    0    0    0    0    0
M16_1 M17_1 M18_1 M19_1 M20_1 M21_1 M22_1 M23_1 M24_1 M25_1 M26_1 M27_1 M28_1 M29_1 M30_1
    0    0    0    0    0    0    0    0    0    0    0    0    0    0    0
...
W41_1 W42_1 W43_1 W44_1 W45_1 W46_1 W47_1 W48_1 W49_1 W50_1 M1_2 M2_2 M3_2 M4_2 M5_2
    0    0    0    0    0    0    0    0    0    0    1    1    1    1    1
  M6_2 M7_2 M8_2 M9_2 M10_2 M11_2 M12_2 M13_2 M14_2 M15_2 M16_2 M17_2 M18_2 M19_2 M20_2
    1    1    1    1    1    1    1    1    1    1    1    1    1    1    1
```

6.9 get.creating.type

This function extracts the creating type of each individual – this is mostly applicable when using the web-based application of the package. Here following coding is used:

- 0 – Founder
- 1 – Selection
- 2 – Reproduction
- 3 – Recombination
- 4 – Selfing
- 5 – DH-Production
- 6 – Cloning
- 7 – Combine
- 8 – Aging
- 9 – Split

```
> get.creating.type(population, gen=1:3)
M1_1 M2_1 M3_1 M4_1 M5_1 M6_1 M7_1 M8_1 M9_1 M10_1 M11_1 M12_1 M13_1 M14_1 M15_1
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
M16_1 M17_1 M18_1 M19_1 M20_1 M21_1 M22_1 M23_1 M24_1 M25_1 M26_1 M27_1 M28_1 M29_1 M30_1
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
...
W31_2 W32_2 W33_2 W34_2 W35_2 W36_2 W37_2 W38_2 W39_2 W40_2 W41_2 W42_2 W43_2 W44_2 W45_2
2 2 2 2 2 2 2 2 2 2 2 2 2 2 2
W46_2 W47_2 W48_2 W49_2 W50_2 M1_3 M2_3 M3_3 M4_3 M5_3 M6_3 M7_3 M8_3 M9_3 M10_3
2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
```

6.10 get.cullingtime

This function extracts the time of culling of each individual – this is mostly applicable when using the web-based application of the package.

6.11 get.individual.loc

Function to derive the position in the stored population-list.

```
> get.individual.loc(population, gen=1)
      generation sex individual nr.
M1_1           1   1           1
M2_1           1   1           2
M3_1           1   1           3
M4_1           1   1           4
M5_1           1   1           5
```

6.12 get.vcf

Function to export genomic data in a vcf-file (currently using the synbreed-package but more efficient implementation including stored bp etc. is planned). Set **path** to the path you want to write to:

```
##fileformat=VCFv4.1
##filedate= 17980
##source="write.vcf of R-synbreed"
##FORMAT=<ID=GT,Number=1,Type=String,Description="Genotype">
#CHROM POS ID REF ALT QUAL FILTER INFO FORMAT M1_3_set2 M10_3_set2 M2_3_set2 M3_3_set2
chr1 . Chr1SNP1 A G . PASS . GT 0|0 0|1 1|0 0|0 0|0 0|0 0|0 0|0 0|0 0|0
chr1 . Chr1SNP2 A G . PASS . GT 1|0 0|1 1|1 0|1 0|1 0|1 0|0 0|0 1|0 0|0
chr1 . Chr1SNP3 A G . PASS . GT 0|1 1|0 0|0 1|0 0|0 1|0 1|1 0|1 0|1 0|0
chr1 . Chr1SNP4 A G . PASS . GT 1|0 0|1 1|0 1|1 0|1 1|1 0|0 1|0 0|0 0|0
chr1 . Chr1SNP5 A G . PASS . GT 0|0 0|1 0|0 0|0 0|0 0|0 0|0 0|0 0|0 0|0
```

6.13 get.pedmap

Function to export genomic data in a ped and a map-file (PLINK format (Purcell et al. 2007)). The first of the two columns of each marker is representing the first haplotype of the individual. Set **path** to the path you want to write to:

```

1 1 0 0 0 0 C C C C C C C C A A A C C C A C A C A A C C A C A
1 2 0 0 0 0 A A A A A A A A A A A A C C A A A A A A C C C A
1 3 0 0 0 0 A C A A C C C C C C A A A A A A C A C C A A A C C

1 11 0 0 0 0 A C A A C C C C C C A A A A C A C C C C A C A C

1 SNP1 0 0
1 SNP2 0 0
1 SNP3 0 0
1 SNP4 0 0
1 SNP5 0 0
1 SNP6 0 0
1 SNP7 0 0
1 SNP8 0 0
1 SNP9 0 0

```

6.14 get.database

Function to merge **gen**, **database** and **cohorts** –info into a joint database. This is only needed internally – as it is the only internal get.X function it is still mentioned here for completeness.

```

> get.database(population, gen=1, cohorts="Selected_bulls")
      start end
[1,] 1 1      1 50
[2,] 1 2      1 50
[3,] 3 1      1 10

```

7 Importing information to the population-list

7.1 Insert.bve

To manually insert breeding values (type="bve"), true genetic values (type="bv") or phenotypes (type="pheno") use the function insert.bve. Output is a modified population list. In case new phenotypes are observed this is counted as **count** observations. In case bve are changed it is assumed that genotyping was necessary unless **count** is set to 0. This is only relevant for economic calculations.

New observations are entered in the parameter **bves** with the first column coding the individual and the others containing values for the traits:

```
> bves
      Individual Name Trait 1 Trait 2
[1,] "M1_1"          "101.5" "104.2"
[2,] "M2_1"          "102"    "98.9"
[3,] "M3_1"          "99.7"   "98.4"
[4,] "M4_1"          "98.2"   "101.2"
[5,] "M5_1"          "103.8" "101.1"
> population <- insert.bve(population, bves)
```

Structure of individual names is the same in all export functions (sex ["M"/"F"], individual number [1,2,...], and generation [1,2,...]). It is recommend to just use the names as they are exported via *get.geno* ect..

8 Data structure of the population list

All information regarding the breeding program are stored in a population list (R-object: list) which is modified by each run of *breeding.diploid()* and *creating.diploid()*. The population list contains matrices, inside of lists, inside of lists, inside of lists, inside of lists, inside of lists, inside of lists (you get the point!) – when understanding the structure behind it is actually not that bad, luckily you do not have to understand the structure behind for most applications since you can use exporting function discussed in section 6.

The list contains two major parts - \$info ((or [[1]])) and \$breeding ((or [[2]])):

8.1 \$info

\$info contains all general information concerning genetic architecture, size of the program and internal information needed to perform the simulations. Each entry is names according to what it is supposed to contain.

schlather.slot1	Internal variable for miraculix (cre: M. Schlather)
chromosome	Number of chromosomes in the population list
snp	Number of SNPs per chromosome
position	Position (in Morgan) on the chromosome for each marker
snp.base	Major/Minor Allele (e.g. characters since internally 0/1 is used)
snp.position	Overall position in the genome (ongoing over chromosomes)
length	Length of each chromosome
length.total	Cumulative length of chromosomes
func	It's just FALSE – placeholder for later
size	Size of each group (generation/sex)
bve	Coding if breeding values are simulated
bv.calculated	Coding if breeding values are calculated for the founders (will be after first run of <i>breeding.diploid()</i>)
breeding.totals	Recap of each run of <i>breeding.diploid()</i> (if stored)
bve.data	Recap of each breeding value estimation (if stored)
bve.nr	Number of traits (with QTLs behind) to consider

bv.random	Coding which traits have underlying QTLs behind
bv.random.variance	Genetic variance for traits with no QTLs behind
snps.equidistant	Are SNPs equidistant on every chromosome (speed up!)
origin.gen	List of founding generations (with stored haplotypes)
cumsnp	Cumulative sum of SNP number (just to save computational time)
bp	Physical position of each marker (bp)
snp.name	Name of each marker
bv.mult.factor	(bv) * this
bv.poly.factor	(bv) ^ this
base.bv	This + QTL_effects
bv.calc	Number of total traits (including those with no QTL behind)
real.bv.length	Traits with (additive/multiplicative/dice-effects)
sex	Sex of the founders added in <i>creation.diploid</i>
miraculix	Coding if miraculix was used to generate the data – only miraculix users will be able to work with those population lists
cohorts	List of all cohorts with name and position in the population list
real.bv.add	Lists with an overview of all single marker QTLs for each trait
real.bv.mult	Lists with an overview of all two marker QTLs for each trait
real.bv.dice	Lists with an overview of all three+ marker QTLs for each trait
pheno.correlation	Correlation matrix of the environmental variance between traits
bv.correlation	Correlation matrix of the genetic variance between traits (only for non-QTL traits)
effect.p	Markers involved as QTL in any trait
store.effect.freq	Frequency of each marker in each generation
last.sigma.e	Last used environmental variance
comp.times	Computation times needed in each use of <i>breeding.diploid()</i> (if stored)
comp.times.bve	Computation times needed in the breeding value estimation in each use of <i>breeding.diploid()</i> (if stored)
Next.animal	ID of the next individual to generate
Culling.stats	Information on the culling reason of each individual (mostly relevant for the web-interface)

8.2 \$breeding

\$breeding contains all relevant information concerning the individuals of the breeding scheme. For efficiency purposes a lot of this is internally coded or computed on-the-fly.

Individuals are sorted according to generation, sex and individual number. In case data has to be stored for both male and female (or father/mother) there will be two entries with the first one being the male (Have to talk with the equality commissioner about that!).

\$breeding[[generation]][[sex]][[individual nr.]] ((or [[2]][[generation]][[sex]][[individual nr.]])

8.2.1 Storage per generation

\$breeding[[generation]][[3,4]]	Estimated breeding values of males (3) and females (4)
\$breeding[[generation]][[5,6]]	Class of males (5) and females (6)
\$breeding[[generation]][[7,8]]	Underlying “true” genetic values of males (7) and females (8)
\$breeding[[generation]][[9,10]]	Observed phenotypes for males (9) and females (10)
\$breeding[[generation]][[11,12]]	Time point of generation for male (11) and females (12)
\$breeding[[generation]][[13,14]]	Creating type of generation for males(13) and females (13) This is only relevant for the web-based application
\$breeding[[generation]][[15,16]]	Individual IDs for male (15) and females (16)
\$breeding[[generation]][[17,18]]	Time of culling for male(17) and female (18) individuals
\$breeding[[generation]][[19,20]]	Reliability estimated for male (19) and females (20)
\$breeding[[generation]][[21,22]]	Last applied selection index (mostly relevant for complex selection indices like (Miesenberger 1997)

```

```

8.2.2 Storage per individual

\$breeding[[generation]][[sex]][[individual nr.]]...

[[1,2]]	Points of recombination on the first (1) and second (2) chromosome set
[[3,4]]	Points of mutations
[[5,6]]	Efficiently stored origins of segments between two points of recombination. Decoding using <i>decodeOrigins()</i> (miraculix) / <i>decodeOriginsR()</i> (else). Output in <i>get.recombi()</i> is automatically decoded
[[7,8]]	Father / Mother
[[9,10]]	Efficiently stored haplotypes (if it is a founder – else empty)
[[11,12]]	Storage of duplications (long not used!)
[[13,14]]	Storage of history of recombinations
[[15]]	How often a phenotype was generated for the individual
[[16]]	Is the individual genotyped
[[17]]	True breeding value before gene editing
[[18]]	Generation of death and previous class
[[19]]	Share of the genetic material of the grandfather of the father inherited
[[20]]	Share of the genetic material of the grandfather of the mother inherited
[[21]]	List of all individuals with the same id.

```

9 Utility functions

Since the inclusion of miraculix, I did not need many utility functions any more – older version of function to show development of allele frequencies and others still exists but need modifications. Just tell me if you wish to have a certain function to help you with the package.

9.1 bv.development

This function will generate a plot showing the development of breeding values and phenotypes over generations. 95% confidence bands are included in a dotted line:

Which groups to display is selected via the parameters **gen**, **database** & **cohorts**. In case the user interface was used to generate the population list set **json** to TRUE to automatically display all selected cohorts. Confidence bands are drawn for “bv” (1), “bve” (2) & “pheno”(3) – to change the quantile use the parameter **quantile** (default: 0.95), to exclude selected the for with to draw a confidence band via the parameter **confidence** (default: c(1,2,3)). Groups with only zeros are ignored on default – if you want lines to be included for all selected cohorts set **ignore.zero** to FALSE.

To display the time point, the creating type, the sex, and cohort name set **display.time.point**, **display.creating.type**, **display.cohort.name**, **display.sex** to TRUE. In case the generating interface between groups is highly heterozygous it might be useful to use **equal.spacing** between displayed cohorts. To not display the line displaying a long-term trend of the breeding values set **display.line** to FALSE.

```

population <- json.simulation(total = ex_json)
bv.development(population, json=TRUE, bvrow=1, confidence = 1, development = 1,
               display.creating.type = TRUE, display.sex = TRUE,
               display.cohort.name = TRUE)

```

9.2 bv.development.box

This function will generate a plot displaying the development of breeding values with a boxplot for each selected **gen**, **database**, **cohorts**. In case the user-interface was used to generate the population set **json** to TRUE to automatically display all selected cohorts. To only display a subset of trait set **bvrow** to those traits. To display phenotypes or breeding value estimations for the individuals instead of breeding values, set **display** to “pheno” / “bve”.

In case the user interface was used to generate the population, one can display which cohorts where generated by which other cohort (via selection or reproduction) by setting **display.selection** and **display.reproduction** to TRUE.

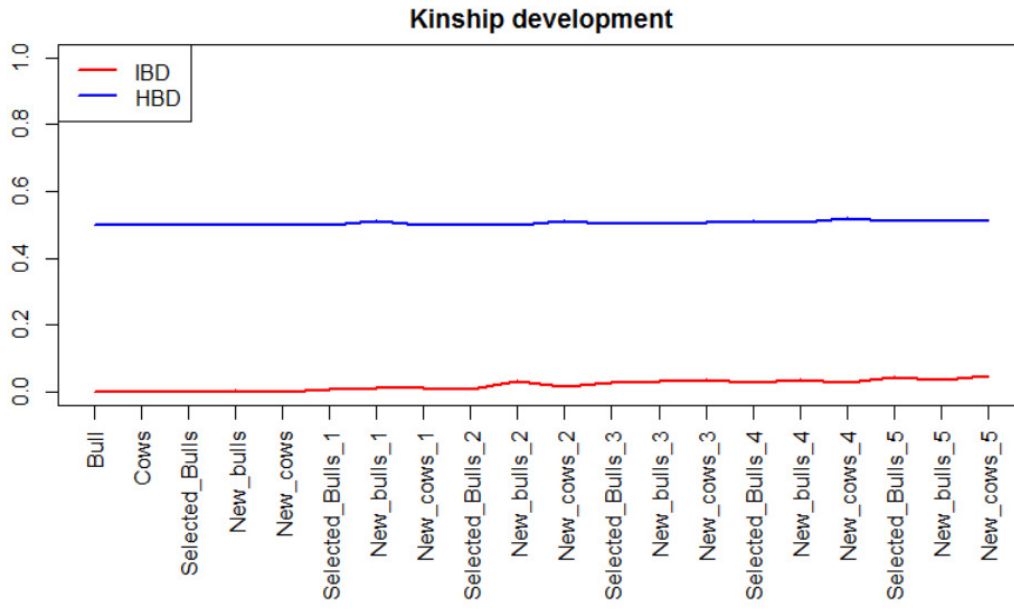

```
population <- json.simulation(total = ex_json)
bv.development.box(population, json=TRUE, bvrow=1)
```

9.3 Kinship.development

Function to display the development of kinship over different gen, database, cohorts. Internally `kinship.emp.fast` is used and same optional parameters can be used to improve computation time / accuracy.

```
population <- json.simulation(total = ex_json)
kinship.development(population, json=TRUE, display.cohort.name = TRUE)
```

9.4 Kinship.emp / kinship.emp.fast

These functions can be used to derive empirical kinship between a set of individuals. Either directly supply a list containing all stored information for the respective individuals via the parameter **animals** or selected them by usage of **gen**, **database**, **cohorts**. In that case the **population** list needs to also be provided.

On default this call lead to all pairwise relations being evaluated. For a quick evaluation use `kinship.emp.fast()` and provide the total number of pairwise relationships (**ibd.obs**) and relations with the individual with itself (**hbd.obs**).

9.5 Kinship.exp

This function can be used to derive the expected kinship between individuals. To how many generations are used back use **prev.gen**. On default it's assumed all individuals before are unrelated. Alternatively, one can provide a **kinship.matrix** the individuals of the first generation via **first.individuals**. It should be noted that there are more efficient ways to derive a pedigree matrix than this – alternatively one can export the pedigree via `get.pedigree()` and use that as input for breedR or tools outside of R.

9.6 analyze.population

With this function, one can analyze the allele frequency of a specific marker over time. Select the marker to analyze via parameters **chromosome** & **snp**. To selected with generations to compare use **gen, database, cohorts**.

```
population <- json.simulation(total = ex_json)
analyze.population(population, 5, 2, gen=1:13)
```

	[,1]	[,2]	[,3]	[,4]	[,5]	[,6]	[,7]	[,8]	[,9]	[,10]	[,11]	[,12]	[,13]
[1,]	4	2	1	0	3	1	3	0	4	1	4	1	5
[2,]	55	5	49	7	41	8	63	6	47	2	47	5	57
[3,]	141	18	150	18	156	16	134	19	149	22	149	19	138

9.7 new.base.generation

With rising number of generations the number of points of recombinations to store is increasing. For efficient storing it can make sense to compute and store haplotypes for a later generation and use those individuals as a new founder generation. For this use *new.base.generation()* and select the new base generation via the parameter **base.gen**. To further reduce memory needs and computation time you can additionally delete data of previous generations via **delete.previous.gen**, **delete.breeding.totals** and **delete.bve.data**.

9.8 creating.trait

With this function one can generate additional traits for the base population without the need to add genetic datasets. Functionality is the same as *creating.diploid()* otherwise.

It is planned to incorporate this in an improved version of this in *creating.diploid()* - Coming soon...

9.9 ensembl.map

Via this functions genetic maps provided in Ensembl (<https://www.ensembl.org/index.html> & <http://plants.ensembl.org/index.html>) can be imported. Internally the package biomaRt is used – for guidelines on how to install this package we refer to <https://bioconductor.org/packages/release/bioc/html/biomaRt.html>.

Naming of parameters is orientated according to the biomaRt package. Set **dataset** to the dataset you want to access (e.g. for cattle-SNPs: "btaurus_snp") – for a list of possible datasets run this function with **export.datasets** set to TRUE.

To import a subset of all markers use the parameter filter and **filter.values**. To limited the markers to a specific SNP-chip just set **filter.values** to the name of the chip (e.g. **filter.values**="Illumina BovineSNP50 BeadChip"). Names of potential filters for a dataset can be exported by setting **export.filters** to TRUE.

For a list of map that are already included in MoBPS and the associated data package MoBPS_maps we refer to section 12.

```
cattle_map <- ensembl.map(dataset="btaurus_snp", filter.values="Illumina BovineSNP50 BeadChip")
> cattle_map[1:10,]
      Chromosome SNP-ID      bp      M      freq
[1,] "1"         "rs42778024" "435963" NA NA
[2,] "1"         "rs41609588" "776231" NA NA
[3,] "1"         "rs108982244" "907810" NA NA
[4,] "1"         "rs29026917" "1073496" NA NA
[5,] "1"         "rs29015852" "1150763" NA NA
[6,] "1"         "rs108981857" "1566539" NA NA
[7,] "1"         "rs108994381" "1695632" NA NA
[8,] "1"         "rs41635940" "1929664" NA NA
[9,] "1"         "rs41255293" "2082139" NA NA
[10,] "1"        "rs41580909" "2235492" NA NA
```

9.10 compute.costs

To calculate the costs of the currently simulated breeding program use the function *compute.costs()*. Currently implemented cost factors include the following:

Cost factor	MoBPS -Parameter	Default
Phenotyping	phenotyping.costs	10
Genotyping	genotyping.costs	100
Housing/Field costs	Housing.costs	0
Fixed costs	fix.costs	0
Annual costs	fix.costs.annual	0
Profit per BV	profit.per.bv	1

Note that all default settings are basically chosen at random and should be modified when analyzing a real breeding program. In case costs/gains between sexes are different, use a vector. To separate between generations use a matrix with each row coding costs/gains per generation.

To only calculate the resulting costs of some generations/cohorts use `database/gen`.

To model an interest rate set **interest.rate** (default: 1 – meaning $i = 0\%$. We here assume inputs of the form $1 + i$) – with costs/gain changed according to a base generation (**base.gen** – default: 1)

```
> compute.costs(population, gen=1:10)
[1] -63014.02 -242252.85 -274059.21 -144566.68 12944.92 132774.58 165916.47 299725.18 339646.66 510074.31
```

9.11 compute.costs.cohorts

The functionality of `compute.costs.cohorts()` is similar to `compute.costs()` with the added benefit of usability with input parameters provided in our user-interface. Input parameters include **phenotyping.costs**, **genotyping.costs**, **housing.costs**, **fix.costs**, **fix.costs.annual**, **profit.per.bv**, **interest.rate**. In case the user interface is provided considered groups (gen, database, cohorts) are automatically assigned to their time point of creation for discounting.

9.12 summary

The population list generated via *creating.diploid()* and *breeding.diploid()* is of class “population”. Application of the generic function *summary* leads to an overview of the population list including the number of individuals, cohorts, structure of the genome and traits:

```
> summary(population)
Population size:
Total: 13255 Individuals
Of which 1255 are male and 12000 are female.
There are 2 generations
and 35 unique cohorts.

Genome Info:
There are 31 unique chromosomes.
In total there are 45613 SNPs.
The genome has a total length of 0.01802583 Morgan.
The genome has a physical size of about: 7e-04 GB
Trait Info: There are 1 modelled traits.
Of which 1 have underlying QTL.
Trait names are: Pheno 1
Genetics of traits are uncorrelated.
There are no interactions between enviromental effects.
```

9.13 pedmap.to.phasedbeaglevcf

The standard input of MoBPS are haplotypes (not genotypes!). In case of using own genomic data it is highly encourages to perform genomic phased before using the dataset as an input. In this function a routine pipeline to generate a phased dataset is executed. In this pipeline BEAGLE 5.0 (<https://faculty.washington.edu/browning/beagle/beagle.html>) and PLINK 1.9 (<https://www.cog-genomics.org/plink/1.9/>) are used. Additional file are generated in a selected directory. Path for all three have to be provided in **beagle_jar**, **plink_dir**, **db_dir**. Input can either be a dataset in PLINK format (**ped_path**, **map_path**) or a vcf-file (**vcf_path**). Defaults are all chosen to work on the webserver for our web-interface (Chapter 14). Phasing can also be directly performed in the web-interface.

10 Memory and computation times

Critical parts of MoBPS concerning memory requirements and computation times can be performed using the associated R-package *miraculix*. By using SSE2 operations and bit-wise storing computation speed can be massively increased leading to about 10 times faster matrix multiplications than the regular R implementation while needing only 1/16 of the regularly needed memory.

To speed up commutation of the breeding value estimation one can use multiple cores by the usage of **miraculix.cores** (default: 1) or in case *miraculix* is not active **ncore**. To parallelize generation of new individuals set **parallel.generation** to TRUE and set the number of cores used via **ncore.generation**. This will only lead to significant improvement in computation time for the generation of a lot of individuals. Even when using a single core ~1'000 individuals are generated per second. The packages *doParallel* (Microsoft Corporation and Steve Weston 2018) and *doRNG* (Renaud Gaujoux 2018) are used for parallelization in R.

11 List of input parameters in breeding.diploid()

For a description of each parameter we refer to the use of the help function in R (*?breeding.diploid*) and/or other sections of this Guidelines.

<u>Parameter</u>	<u>Default</u>	<u>options</u>
population	NULL	A previous population list
mutation.rate	10 ⁻⁵	Value between 0 and 1
remutation.rate	10 ⁻⁵	Value between 0 and 1
recombination.rate	1	Any positive numeric
selection.m	"random"	"function"
selection.f	selection.m	"random", "function"
new.selection.calculation	TRUE	FALSE
selection.function.matrix	NULL	Don't touch – will be removed
selection.size	C(0,0)	Vector with two non-negative values
breeding.size	0	Positive number // 2 element vector (male/female)
breeding.sex	0.5	Value between 0 and 1
breeding.sex.random	FALSE	TRUE
used.generation.m	1	Vector with at most generation elements
used.generation.f	used.generation.m	So.
class.m	0	Vector with all classes to consider
class.f	class.m	Vector with all classes to consider
add.gen	0 (will lead to added generation)	Value between 1 and number of generations
recom.f.indicator	NULL	Not necessary (use modified marker position instead!)
recom.f.polynom	NULL	Not necessary (use modified marker position instead!)
duplication.rate	0	
duplication.length	0.01	Duplication modelling needs changes!
duplication.recombination	1	
same.sex.active	FALSE	TRUE
new.class	0	Numeric value (ideally positive integer; -1 is reserved for dead individuals)
bve	FALSE	TRUE
bve.direct.est	TRUE	FALSE

culling.index	0	Any weights – use a vector with length equal to number of traits, "lastindex"
gen.architecture.m	0	Natural number (select one of the previously stored architectures)
gen.architecture.f	gen.architecture.m	Natural number (select one of the previously stored architectures)
ncore	1	Natural number
Z.integer	FALSE	TRUE
store.effect.freq	TRUE	FALSE
backend	"doParallel"	„doMPI“
randomSeed	NULL	natural number
randomSeed.generation	NULL	Natural number
Rprof	FALSE	TRUE
miraculix	FALSE	TRUE (automatically activated when miraculix is used is <i>creating.diploid()</i>)
miraculix.mult	NULL (leading to FALSE)	TRUE / FALSE
fast.compiler	0	3 (For R >= 3.4 this is default in R)
miraculix.cores	1	natrual number
store.bve.parameter	FALSE	TRUE
print.error.sources	FALSE	TRUE
chol.miraculix	FALSE	TRUE
bve.insert.gen	NULL	1:3

bve.insert.database	NULL	<div> <div>Generation sex</div> <div> <div>[1,]</div> <div>1</div> <div>2</div> </div> <div> <div>[2,]</div> <div>5</div> <div>1</div> </div> </div>
bve.insert.cohorts	NULL	c("Founder_M", "F1")
best.selection.ratio.m	1	positive numeric value
best.selection.ratio.f	best.selection.ratio.m	positive numeric value
best.selection.criteria.m	"bv"	"bve", "pheno"
best.selection.criteria.f	best.selection.criteria.m	"bve", "pheno"
best.selection.manual.ratio.m	NULL	positive numeric value
best.selection.manual.ratio.f	best.selection.manual.ratio.m	positive numeric value
bve.class	NULL (take all!)	vector containing numeric values
parallel.generation	FALSE	TRUE
ncore.generation	1	Positive numeric value
name.cohort	NULL	"Founders" or any other character string
add.class.cohorts	TRUE	FALSE
display.progress	TRUE	FALSE
ignore.best	C(0,0)	Any two element vector (first male, second female)
combine	FALSE	TRUE
repeat.mating	1	Positive numeric value
time.point	0	Positive numeric value (this will be automatically processed in the web-based-application)
creating.type	0	<p>This is automatically stored in the web-based-application</p> <p># 0 – Founder</p> <p># 1 – Selection</p> <p># 2 – Reproduction</p> <p># 3 – Recombination</p> <p># 4 – Selfing</p> <p># 5 – DH-Production</p> <p># 6 – Cloning</p> <p># 7 – Combine</p> <p># 8 – Aging</p> <p># 9 – Split</p>

12 List of input parameters in creating.diploid()

For a description of each parameter we refer to the use of the help function in R (*?creating.diploid*) and/or other sections of this Guidelines.

<u>Parameter</u>	<u>Default</u>	<u>options</u>
population	NULL (will lead to “random”)	A previous population list
dataset	“random”	SNP-dataset (One haplotype per colum), “random”, “all0”, “homorandom”, “allhetero”
nsnp	0	Positive integer value
nindi	0	Positive integer value
ccf	NULL	Path to a vcf-file
map	NULL	Matrix with up to 5 colums containing (chr.nr, snp.name, bp, position in Morgan, allele freq). Rest will be set to NULL/NA. For more see section 13
chr.nr	NULL (all markers on the same chromosome)	Vector containing the chromosome for each generated marker
bp	NULL	Vector containing the base-pair for each generated marker
snp.name	NULL	Vector containing the snp-name for each generated marker
bpcm.conversion	0	Recommendations: For human: 100.000.000 For chicken: 30.000.000
chromosome.length	NULL (will lead to 5M)	Positive numeric value
freq	“beta”	Numeric value or vector for each marker
beta.shape1	1	Positive numeric value
beta.shape2	1	Positive numeric value
sex.s	“fixed”	“random”, vector containing the sex of each newly added individual.
share.genotyped	1	Numeric value between 0 and 1
genotyped.s	NULL	vector containing the sex of each newly added individual.
add.chromosome	FALSE	TRUE
generation	1	Positive integer value (no empty generations inbetween!)
class	0	Numeric value (positive integer recommended)
sex.quota	0.5	Numeric value between 0 and 1

snps.equidistant	NULL (will be TRUE if no other way to derive Morgan-position is provided)	FALSE/TRUE
change.order	FALSE	TRUE
position.scaling	FALSE	TRUE
length.before	5	Positive numeric value
length.behind	5	Positive numeric value
hom0	NULL (automatically derived)	Vector containing major allele for each generated marker.
hom1	NULL (automatically derived)	Vector containing minor allele for each generated marker.
miraculix	TRUE	FALSE
bit.storing	FALSE	TRUE (this is less efficient than miraculix but does not rely on C-code)
nbits	30	Integer value between 1 and 30
bv.total	0 (automatically set according to traits provided)	Integer value. If higher than the number of traits simulate traits based on pedigree/inbreeding rates
trait.name	NULL	Vector containing the names of the traits (e.g. "milk")
real.bv.add	NULL	List with each element containing effect matrices
real.bv.mult	NULL	List with each element containing effect matrices
real.bv.dice	NULL	List with each element containing effect lists
n.additive	0	Positive integer value
n.dominant	0	Positive integer value
n.qualitative	0	Positive integer value
n.quantitative	0	Positive integer value
var.additive.l	NULL	List containing a single numeric value or vector with variances for each trait
var.dominant.l	NULL	List containing a single numeric value or vector with variances for each trait
var.qualitative.l	NULL	List containing a single numeric value or vector with variances for each trait
var.quantitative.l	NULL	List containing a single numeric value or vector with variances for each trait
exclude.snps	NULL	Vector containing marker positions with no simulated random effects
shuffle.traits	NULL	TRUE
shuffle.cor	NULL	Correlation matrix for the traits to shuffle

replace.real.bv	FALSE	TRUE
name.cohort	NULL	Character string
skip.rest	FALSE	TRUE (INTERNAL PARAMETER!)
randomSeed	NULL	Integer value
template.chip	NULL	"cattle", "chicken", "pig", "sheep", "maize"
time.point	0	Positive numeric value (this will be automatically processed in the web-based-application)
creating.type	0	This is automatically stored in the web-based-application # 0 – Founder # 1 – Selection # 2 – Reproduction # 3 – Recombination # 4 – Selfing # 5 – DH-Production # 6 – Cloning # 7 – Combine # 8 – Aging # 9 – Split
remove.invalid.qtl	TRUE	FALSE

13 List of datasets included in the package

MoBPS does contain a variety of maps that are preimported from Ensembl since the actual import takes quite long for bigger map-files. In case you feel a certain map is missing feel free to contact us to we can add it to the tool. Maps are available in the associated R-package MoBPS_maps. Only map_chicken1, map_cattle1 and map_maize1 are included in MoBPS itself. To use a specific map use it as an input for the parameter **map** in *creating.diploid()*.

In addition to all those maps an exemplary json-file (**ex_json**) generated by a recent version of our interface is included for text use in *json.simulation()* and other function that utilize datasets generated by *json.simulation()*. Note that this file is automatically generated via the user-interface and you do not have to worry about its structure.

Dataset name	Corresponding Chip	Number of Markers	Contains:		
			1. Physical position		
			2. Morgan position		
			3. allele frequency		
Map_pig1	Axiom Genotyping Array	590'318			
Map_pig2	GGP Porcine HD	63'113			
Map_pig3	GGP Porcine LD	8'624			

Map_pig4	Illumina_PorcineSNP60	55'684			
Map_chicken1	Affymetrix Chicken600K Array	547'024			
Map_chicken2	Affymetrix Chicken600K Array (diversity subset)	293'251			
Map_chicken3	Affymetrix Chicken600K Array (50k subset)	50'000			
Map_cattle1	Illumina BovineSNP50 BeadChip	45'613			
Map_cattle2	Illumina BovineHD BeadChip	727'605			
Map_cattle3	Illumina BovineLD BeadChip	6'600			
Map_cattle4	Genotyping chip variations	732'645			
Map_horse1	Illumina EquineSNP50 BeadChip	51'105			
Map_sheep1	IlluminaOvineHDSNP	575'256			
Map_sheep2	IlluminaOvineSNP50	46'545			
Map_sheep3	Genotyping chip variants	580'661			
Map_goat1	Illumina_GoatSNP50	55'050			
Map_human1	Affy GeneChip500K	483'418			
Map_human2	Illumina_1M-duo	1'122'013			
Map_human3	Illumina_HumanHap550	545'902			
Map_maize1	Affymetrix Axiom Maize Genotyping Array	501'124			
Map_wheat1	Subset of a 55k chip from (Liu et al. 2018)	12'109			
Map_wheat2	Subset of a 90K chip from (Wen et al. 2017)	29'692			
Map_sorghum1	Subset of a 90k chip from (Bekele et al. 2013)	3'000			

Ex_json – the first few rows. Do not bother trying to understand it. *Json.simulation()* will do the job for you:

```

```

14 User-interface

The development of the user-interface of MoBPS is a joint project of Torsten Pook, Amudha Ganesa, Ngoc-Thuy Ha, Lisa Büttgen and Henner Simianer (All: Department of Animal Sciences, Center for

Integrated Breeding Research, University of [Goettingen](#), [Goettingen](#), 37075, Germany) that will have its own user-manual.

The user-interface is currently in active development. There is **no publically available version** as we first have to figure out details about user-login, computation resources etc. before making it publically available. A stable version of the interface does exist that is used internal, for teaching and similar. In case you have a given simulation you want to perform feel free to contact us for possible collaboration (Torsten.pook@uni-goettingen.de). When looking through the openly-available code you will find code snippets that are only relevant for the interface (*json.simulation()*). At the current state, this chapter can mostly be seen as a news page on the current stage of development.

Main goal of the user-interface is the usage of the R-package without the need of programming skills in R or knowledge of the details of the package to set up your simulation. Note that the interface will not be able to grasp the full functionality/efficiency of the R-package but the goal is to get close. Input parameters can be entered in a web-based application (java-script) – especially the breeding scheme can be entered in an intuitive way via nodes (cohorts of individuals) and edges (breeding & selection processes).

Simulations can be directly started via the web-interface with a server hosted from Goettingen. We can provide resources for smaller simulations but for bigger simulations export of the generated breeding scheme to a json-file is required that can then be run via *json.simulation()* in R. The details on user-login structure are still in planning.

15 Commonly used word definitions

Group: Group of individuals with the same sex and belonging to the same generation

Cohort: Group of individuals with the same sex generated in a single run of *breeding.diploid()*

Class: Auxiliary variable to classify individuals in an additional dimension (besides sex & generation)

Founder: Founder individuals are the start-point of a simulation and all individuals in the population can be traced back to the founders. Because of this only for those individuals genotype/haplotype data has to be saved.

16 Exemplary scripts

16.1 Simulation of a MAGIC population in maize

We here show how to perform an exemplary simulation of a MAGIC population in maize with a mating scheme given in (Zheng et al. 2015) – cf. adjacent Figure.

Since default settings in MoBPS are to always use the last generation anyway the needed code is quite short even without cohort mode. For the sake of completeness, we provide a cohort version for the script as well.

In term of computation time this simulation with a 15M genome, 32k SNPs and a total of 780 individuals took 2 seconds on one core of my local maschine without the usage of miraculix.

Non-cohort-modus:

```
# Generation of 20 fully-homozygous founders lines
# All plants are stored as male individuals (sex=0)
population <- creating.diploid(nindi = 20, sex.quota = 0, template.chip = "maize"
,
                                dataset = "homorandom")

# Simulate matings between all founders.
# Each plan is involved in exactly 19 matings.
population <- breeding.diploid(population, breeding.size = c(190,0),
                                breeding.all.combination = TRUE,
                                selection.size = c(20,0), max.offspring = 19)

# Simulate matings between plants of the last generation.
# Each plant is involved in exactly 2 matings.

population <- breeding.diploid(population, breeding.size = c(190,0),
                                selection.size = c(190,0), same.sex.activ = TRUE,
                                same.sex.sex = 0, max.offspring = 2)
population <- breeding.diploid(population, breeding.size = c(190,0),
                                selection.size = c(190,0), same.sex.activ = TRUE,
                                same.sex.sex = 0, max.offspring = 2)
population <- breeding.diploid(population, breeding.size = c(190,0),
                                selection.size = c(190,0), same.sex.activ = TRUE,
                                same.sex.sex = 0, max.offspring = 2)
```

Cohort-modus:

```
# Generation of 20 fully-homozygous founders lines
# All plants are stored as male individuals (sex=0)
population <- creating.diploid(nindi = 20, sex.quota = 0, template.chip = "maize"
,
                                dataset = "homorandom", name.cohort = "F0")

# Simulate matings between all founders.
# Each plan is involved in exactly 19 matings.
population <- breeding.diploid(population, breeding.size = c(190,0),
                                breeding.all.combination = TRUE,
                                selection.size = c(20,0),
                                best1.from.cohort = "F0", name.cohort = "F1")
```

```

# Simulate matings between plants of the last generation.
# Each plant is involved in exactly 2 matings.

population <- breeding.diploid(population, breeding.size = c(190,0),
                               selection.size = c(190,0), same.sex.activ = TRUE,
                               same.sex.sex = 0, max.offspring = c(2,0),
                               best1.from.cohort = "F1", name.cohort = "F2")
population <- breeding.diploid(population, breeding.size = c(190,0),
                               selection.size = c(190,0), same.sex.activ = TRUE,
                               same.sex.sex = 0, max.offspring = c(2,0),
                               best1.from.cohort = "F2", name.cohort = "F3")
population <- breeding.diploid(population, breeding.size = c(190,0),
                               selection.size = c(190,0), same.sex.activ = TRUE,
                               same.sex.sex = 0, max.offspring = c(2,0),
                               best1.from.cohort = "F3", name.cohort = "F4")

```

16.2 Simulation of Introgression on blue eggshell QTL

We here show how to perform an exemplary simulation of a breeding scheme to perform introgression of a single QTL.

In term of computation time this simulation with a 5M genome, 5k SNPs and a total of 520 individuals took 1.2 seconds on one core of my local maschine without the usage of miraculix.

```

# Generate an input SNP-dataset
# 10 White-Layer (0) (20 haplotypes, 5'000 SNPs)
# 10 Wild population (1) (20 haplotypes, 5'000 SNPs)
dataset1 <- matrix(0, nrow = 5000, ncol = 20)
dataset2 <- matrix(1, nrow = 5000, ncol = 20)

# Generation of a trait
# Columns code: SNP, chromosome, effect 00, effect 01, effect 11
# Blue Eggshell QTL is positioned on SNP 2000, chromosome 1
major_qlt <- c(2000, 1, 0, 10000, 20000)
# In all other positions the white layer genome is assumed to be favorable
# All marker effects combined are smaller than the blue eggshell QTL
rest <- cbind(1:5000, 1, 1, 0.5, 0)
trait <- rbind(major_qlt, rest)

# Generation of the base-population
# First 10 individuals are female (sex=2)
# Next 10 individuals are male (sex=1)
population <- creating.diploid(dataset = cbind(dataset1, dataset2),
                               real.bv.add = trait, name.cohort = "Founders",
                               sex.s = c(rep(2,10), rep(1,10)))

# Simulate random mating:
population <- breeding.diploid(population, breeding.size = c(100,100),
                               selection.size = c(10,10),
                               best1.from.cohort = "Founders_M",
                               best2.from.cohort = "Founders_F",
                               name.cohort = "F1")

# Simulation of matings with selection:
# Top 50 cocks are mated to the 10 founder hens
# Selection of the cocks based on their genomic value ("bv")
# Target: Increase share of white layer while preserving blue egg shell QTL

population <- breeding.diploid(population, breeding.size = c(100,100),
                               selection.size = c(50,10),
                               best1.from.cohort = "F1_M",
                               best2.from.cohort = "Founders_F",

```

```

        name.cohort = "BC1", selection.m = "function",
        selection.criteria.type = "bv")
population <- breeding.diploid(population, breeding.size = c(100,100),
        selection.size = c(50,10),
        best1.from.cohort = "BC1_M",
        best2.from.cohort = "Founders_F",
        name.cohort = "BC2", selection.m = "function",
        selection.criteria.type = "bv")
population <- breeding.diploid(population, breeding.size = c(100,100),
        selection.size = c(50,10),
        best1.from.cohort = "BC2_M",
        best2.from.cohort = "Founders_F",
        name.cohort = "BC3", selection.m = "function",
        selection.criteria.type = "bv")

# Mating of cocks and hens that are heterozygous in blue egg shell QTL
# 25% of resulting offspring should be homozygous in blue egg shell QTL

population <- breeding.diploid(population, breeding.size = c(100,100),
        selection.size = c(50,50),
        best1.from.cohort = "BC3_M",
        best2.from.cohort = "BC3_F",
        name.cohort = "IC", selection.m = "function",
        selection.criteria.type = "bv")

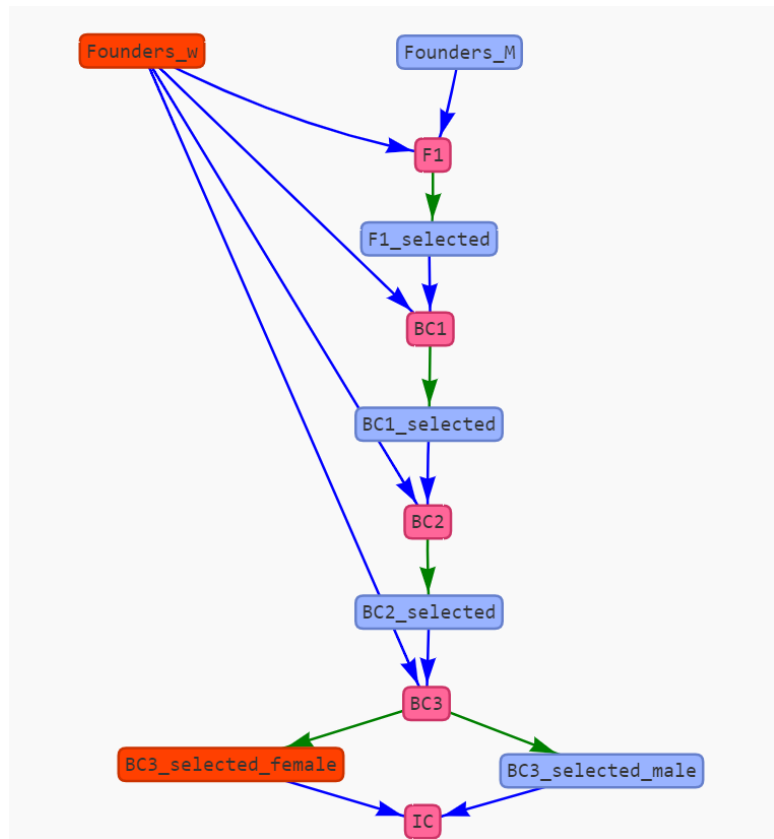

# Check genomic share of wild race in the final generation
genoIC <- get.geno(population, cohorts = "IC_F")
plot(rowSums(genoIC)/200, xlab = "genome", ylab = "frequency of wild allele",
     type = "l")
abline(v = 2000, lwd = 2, col = "red")

```

As expected, the frequency of genetic material stemming from the wild type is higher in the region of the QTL.

16.3 Simulation of gene editing in a cow breeding program

The following script can be used to simulate a breeding program that is utilizing genome editing. Design is chosen according to (Jenko et al. 2015; Simianer et al. 2018). Note that individual numbers are much smaller than in the two references to ensure low computation times. Simulation of 20 generations with 50'000 cows per generation would take ~ 30 hours using 24 cores on the gwdg-hpc (Intel E5-2650 (2X12 core 2.2GHz)).

```
# Generation of a base population:
# 1'000 Founder individuals
# 5'000 SNPs
# 100 additive single marker QTL
population <- creating.diploid(nindi = 1000, nsnp = 5000,
                             n.additive = 100, name.cohort = "Founders")

# Simulation of a random mating generation
# 100 bulls (sex=1), 1'000 cows (sex=2) are generated
population <- breeding.diploid(population, breeding.size = c(100,1000),
                              selection.size = c(500,500),
                              best1.from.cohort = "Founders_M",
                              best2.from.cohort = "Founders_F",
                              name.cohort = "Random")

# Generate 200 offspring of both from the top 5 bulls / 200 cows
# Heritability of the trait is set to 0.5
# only phenotypes previously unobserved cows are generated
population <- breeding.diploid(population, breeding.size = 200,
                              selection.size = c(5,200), bve = TRUE,
                              heritability = 0.5, new.bv.observation =
"non_obs_f",
                              selection.m = "function", name.cohort = "Top",
                              best1.from.cohort = "Random_M",
                              best2.from.cohort = "Random_F")

# Generate additional cows using all cows of the previous generation
# Cows are added to the same generation as the previous simulation
population <- breeding.diploid(population, breeding.size = c(0,900),
                              selection.size = c(5,1000),
                              selection.m = "function", name.cohort = "Sec_F",
                              best1.from.cohort = "Random_M",
                              best2.from.cohort = "Random_F",
                              use.last.sigma.e = TRUE,
                              add.gen = 3)

# Same cycle as before with additional genome editing
# Edits are chosen based on highest effects in rrBLUP
population <- breeding.diploid(population, breeding.size = c(100,100),

                              new.bv.observation = "non_obs_f",
                              selection.m = "function",
                              name.cohort = "Top_Edit",
                              best1.from.cohort = "Top_M",
                              best2.from.cohort = c("Top_F", "Sec_F"),
                              nr.edits = 20, estimate.u = TRUE,
                              use.last.sigma.e = TRUE)

population <- breeding.diploid(population, breeding.size = c(0,900),
                              selection.size = c(5,1000),
                              selection.m = "function", name.cohort = "Sec_Edit",
                              best1.from.cohort = "Top_M",
                              best2.from.cohort = c("Top_F", "Sec_F"),
                              use.last.sigma.e = TRUE, add.gen = 4)

# Just simulate some more phenotypes for the plot (alt. use ne)
population <- breeding.diploid(population, use.last.sigma.e = TRUE,
```

```

new.bv.observation = "non_obs")

bv.development(population, cohorts = c("Founders_F", "Random_F", "Sec_F",
                                       "Top_F", "Sec_Edit", "Top_Edit_F"),
               display.cohort.name = TRUE, display.sex = TRUE, development = 1)

```

16.4 Simulation of a base population with a hard sweep

We here show how to perform an exemplary simulation to generate a base population and a hard sweep.

```

# Generate a starting population with 5000 SNPs and 200 individuals
# and a single chromosome of length 2 Morgan.
population <- creating.diploid(nsnp = 5000, nindi = 200, chromosome.length = 2)

# LD build up via 100 generations of random mating
# Each generation contains 200 individuals
for(index in 1:100){
  population <- breeding.diploid(population, breeding.size = 200,
                                selection.size = c(100,100))
}

# Derive allele frequency and check LD for the last generation:
genotype.check <- get.geno(population, gen = length(population$breeding))
p_i <- rowMeans(genotype.check)/2
ld.decay(population, genotype.dataset = genotype.check, step = 10, max = 500)

```

```

# Simulate a favorable mutation in a previously fixed marker
fixated_markers <- which(p_i==0) # Which markers are fixated

```

```

qtl_posi <- sample(fixated_markers, 1) # Selected a fixated marker in A
trait <- cbind(qtl_posi, 1, 0, 1, 2) # SNP, Chromosome, Effect AA, Effect AB,
# Effect BB
population <- creating.trait(population, real.bv.add = trait)

# Generate a mutation in the first male individual
population <- mutation.intro(population, 101, 1, 1, qtl_posi)

# Simulate generations with selection pressure
# Individuals with the favorable SNP are picked 5 times as often
for(index in 1:25){
  population <- breeding.diploid(population, breeding.size = 200,
                                selection.size = c(100,100),
                                best.selection.ratio.m = 5,
                                best.selection.ratio.f = 5)
}

analyze.population(population, gen = 98:115, chromosome = 1, snp = qtl_posi)

```
